### CS332 Homework 4

1.

Question: Given a graph with  $n$  vertices, how many 4 cliques can it have (at most) ?

If we want to have the maximum number of 4- clique in the graph, the graph should be assumed to be a  $n$ -clique with the vertex size of  $n$ . Thus, the question is reduced to:

Given a  $n$ -clique graph with  $n$  vertex, how many 4 cliques are there? Which is same as asking given an  $n$  vertex graph, how many different subgraphs of size 4 can be chosen ?

As a result, the answer is clearly(using the formula of combination):

$$\begin{aligned}nC4 = n! / 4!(n - 4)! &= n! / 24 * (n-4)! \\ &= 1/24 * ( 1*2*3*4*.....*n / 1*2*3*4.....*n-4) \\ &= 1/24 * (n-3)*(n-2)*(n-1)*n\end{aligned}$$

Note that the value of  $(n-3)*(n-2)*(n-1)*n$  is approximately  $n^4$ . If we are to develop an algorithm to solve this problem, the running time is in  $O(n^4)$ . I will use this running time to solve next question.

Question: show that  $L = \{ G \mid G \text{ contains a 4-clique} \}$  is in P.

To prove a problem is in P, we just have to show that there is an algorithm to solve this problem that runs in polynomial time. As a result, I will present an algorithm `4-clique(G)` that returns True if on input graph G that G contains a 4-clique. The function returns False vice versa.

Helper function: `check(M)` where M is an input of a 4-vertex graph and returns True if graph G is a 4-clique and returns False otherwise.

```
check(M){
  for each vertex in M{
    If this vertex is not connected to all other vertex in M{
      return False
    }
  }
  return True
}
```

Then, put this helper function in the main function `4-clique(G)`:

```
4-clique(G){
  For each subgraphs of 4-vertex{
    If check(subgraph) == True{
      return True
    }
  }
  return false
}
```

Running time for this algorithm: ( assume the number of vertex of G is n)

1. There are  $n^4$  subgraphs to check on input graph G with the size of vertex n. This is proved in the previous question that the running time for this part is  $O(n^4)$ .
2. For each subgraphs, it takes  $16(4 \times 4)$  steps to check if it is a 4-clique. ( Based on different algorithms, this number may be different. However, it is a constant.

It's not hard to see that the running time for this algorithm is  $O(n^4 + 16) = O(n^4)$ . Hence, this problem may be solved in polynomial time.

2.

i.  $J = \{ G \mid G \text{ has } n \text{ vertices and contains an } n/2\text{-clique} \}$ .

I will modify the algorithm above to adapt this question: Instead of checking of each subgraphs of 4 vertices, the algorithm should check each subgraphs of  $n/2$  vertices. To calculate the running time of this algorithm, we need to calculate:

The value  $nC_{n/2}$  is approximately exponential, as a result, this problem is not in P

ii.

Show that  $K = \{ G \mid G \text{ has } n \text{ vertices and contains } n\text{-clique} \}$  is in P.

I will introduce an algorithm  $n\text{-clique}(G)$  that returns true if graph  $G$  of  $n$  vertices contains  $n$ -clique. Note here, the input graph  $G$  is in the format of the adjacency matrix. The algorithm is as follows:

```
n-clique(G){
  for i in range(n){
    for j in range(n){
      If  $G(i,j) == 0 \ \&\& \ (i \neq j)$  {      (Note:  $i = j$  means to check if there is an edge to the vertex
        return False                        itself, which will not be considered to solve this problem.)
      }
    }
  }
  return True
}
```

This algorithm is simple and it just goes through every element in the adjacency matrix. If there is a value of zero, then there are two vertices that are not connected.(return False). When all element in the matrix is checked, then True is returned.

Running time:

The running time of this algorithm  $O(n^2)$  because it simply goes through the  $n \times n$  adjacency matrix. As a result this problem is in P since it can be solved in polynomial time.

### 3. Show that P is closed under intersection

Let  $A_1$  and  $A_2$  where  $A_1 \in P$  and  $A_2 \in P$ . We want to show that  $A_1 \cap A_2$  is also in P.

According to the definition 7.12 from the textbook, a class of languages is in P if it is decidable in polynomial time on a deterministic single-tape Turing machine. As a result :

If  $A_1$  is in P, then there is a deterministic single-tape TM  $M_1$  with complexity of  $O(n^{c_1})$  ( $c_1$  is a constant) that decides  $A_1$

If  $A_2$  is in P, then there is a deterministic single-tape TM  $M_2$  with complexity of  $O(n^{c_2})$  ( $c_2$  is a constant) that decides  $A_2$

The goal for us is to construct a TM  $D$  that decides  $A_1 \cap A_2$  that runs in polynomial time.

$D =$  " On input  $w$ :

1. Run  $M_1$  on input  $w$
2. If  $M_1$  rejects, reject.
3. If  $M_1$  accepts, run  $M_2$  on  $w$
4. If  $M_2$  rejects, reject.
5. If  $M_2$  accepts, accept."

Since  $M_1$  and  $M_2$  runs in polynomial time, the running time for  $D$  is just:

$O(n^{c_1}) + O(n^{c_2})$  which is the same as  $O(n^a)$  where  $a$  is a constant.

As a result,  $D$  also runs in polynomial time and P is closed under intersection.

4.

Prove that  $\text{TIME}(N^4)$  is closed under difference.

According to definition 7.7 from the textbook,  $\text{TIME}(N^4)$  is the collection of all languages that are decidable by an  $O(t(n))$  time Turing machine.

Let  $A_1$  and  $A_2$  be the collection of languages that are decidable by  $O(N^4)$  time Turing machine  $M_1$  and  $M_2$  respectively.

Hence, the goal for us is to construct an  $O(N^4)$  time Turing machine that decides  $A_1 - A_2$

$D =$  " On input  $w$  :

1. Run  $M_2$  on  $w$ , if  $M_2$  accepts, reject
2. If  $M_2$  rejects, Run  $M_1$  on  $w$ ,
3. if  $M_1$  rejects, reject. Otherwise, accept."

Obviously,  $D$  is a decider that decides  $A_1 - A_2$ . We know that  $M_1$  and  $M_2$  runs in  $O(N^4)$ .

The approximate running time for  $D$  is just  $O(N^4) + O(N^4)$  which is the same as  $O(N^4)$ .

We have showed that there exists an  $O(N^4)$  time turing machine that decides  $A_1 - A_2$ . Hence,  $\text{TIME}(N^4)$  is closed under difference.

5. Assume that a function  $f$  is in polynomial time and can be computed in time  $O(n^7)$  and that  $g$  is in polynomial time and can be computed in time  $O(n^2)$ . Prove that  $f$  composed with  $g$ , that is  $f(g(x))$ , can be computed in time  $O(n^{14})$ .

To solve this problem, we need to remember the definition of big "O" notation.

Basically,  $f(x) = O(g(x))$  means that there exists a real number  $c$  and  $x_0$  that  $f(x) \leq c * g(x)$  for all  $x \geq x_0$ .

Hence, In this question:

$$\begin{array}{ll} f(n) \leq c_1 * (n^7) & \text{-----1} \\ g(n) \leq c_2 * (n^2) & \text{-----2} \end{array}$$

Let  $M = g(n) \leq c_2 * (n^2)$  for every  $n > n_0$

Hence,  $f$  composed with  $g$  is :

$$\begin{aligned} f(g(x)) = f(M) &\leq c_1 * (M^7) && \text{using equation (1)} \\ &\leq c_1 * ((c_2 * (n^2))^7) && \text{using equation (2)} \\ &\leq c_1 * (c_2^7) * n^{14} \end{aligned}$$

Since  $c_1$  and  $c_2$  are constant, as a result,  $f(g(x))$  can be computed in  $O(n^{14})$
